# ***Embedding and Extension***

## Embedding and Extension Theorems

Given the derivation sequence and a morphism from  $G_0$  to  $G'_0$

# Embedding and Extension Theorems

is it always possible to extend it?

# Embedding and Extension Theorems

We can build the extension if and only if  $m_2$  is boundary consistent with respect to  $l_1$

# Embedding and Extension Theorems

# Embedding and Extension Theorems

# Embedding and Extension Theorems

# Derived Rule

# Derived Rule

# Embedding and Extension Theorems

Given:

$G_0 \Rightarrow^* G_n$  can be extended to a derivation  $G'_0 \Rightarrow^* G'_n$  if and only if  $m$  is boundary consistent with respect to  $g$ .

***Independence: Local Church-Rosser  
Theorems***

## The problem

Given two rule applications on the same graph  $G$ :

after applying one of them, under which conditions it will be possible to apply the other rule with "the same matching"

## The problem

And given two consecutive rule applications on the same graph G:

up to which point the application of the second rule depends or not on the application of the first rule.

# Example of non parallel independence

# Independence

Two rule applications on the same graph G:

are **parallel independent** if

$$(m_1(L_1) \cap m_2(L_2)) \subseteq (m_1(K_1) \cap m_2(K_2))$$

Two consecutive rule applications on a graph G:

are sequential independent if

$$(m1^*(R1) \cap m2(L2)) \subseteq (m1^*(K1) \cap m2(K2))$$

# Independence

Two rule applications are sequential independent

If the reverse application of the first rule and the second application are parallel independent

# Parallel Independence

Two rule applications on the same graph G:

are parallel independent if

## Local Church-Rosser Theorem

1. Given two parallel independent rule applications of rules  $p_1$  and  $p_2$  on a graph  $G$ :

$$H1 \xleftarrow[m1]{p1} G \xrightarrow[m2]{p2} H2$$

there are applications of  $p_1$  to  $H2$  and of  $p_2$  to  $H1$  such that the final result  $H$  coincides:

2. Given two sequential independent rule applications of rules p1 and p2 on a graph G:

$$G \xrightarrow[m_1]{p_1} H_1 \xrightarrow[m_2]{p_2} H_2$$

there are applications of p1 to H2 and of p2 to H1 such that the final result H coincides:

# ***Parallel Rules and Concurrent Rules***

# Parallel Composition

Given rules

$$L1 \longleftarrow K1 \longrightarrow R1 \quad L2 \longleftarrow K2 \longrightarrow R2$$

Their parallel composition is the rule:

$$L1+L2 \longleftarrow K1+K2 \longrightarrow R1+R2$$

# Theorem of Parallelism

1. Given two parallel independent rule applications of rules  $p_1$  and  $p_2$  on a graph  $G$ :

$$H_1 \xleftarrow[m_1]{p_1} G \xrightarrow[m_2]{p_2} H_2$$

we have:

2. Given two sequential independent rule applications of rules  $p_1$  and  $p_2$  on a graph  $G$ :

$$G \xrightarrow[m_1]{p_1} H_1 \xrightarrow[m_2]{p_2} H_2$$

we have:

# Concurrent Rules

Given two rules  $p_1$  and  $p_2$  and jointly epimorphic morphisms  $m_1$  and  $m_2$  :

$p_1^*_{(m_1, m_2)} p_2 = H_1 \leftarrow K \rightarrow H_2$  is the  $(m_1, m_2)$ -concurrent rule for  $p_1$  and  $p_2$ , if the pushout complements  $D_1$  and  $D_2$  exist.

## Concurrency Theorem

For every transformation  $G1 \Rightarrow_{p1} G2 \Rightarrow_{p2} G3$ , there is a concurrent rule  $p = p1^*_{(m1,m2)} p2$  such that  $G1 \Rightarrow_p G3$ .

# ***Conflicts and Critical Pairs***

## Conflicts and Conflict detection

If we use graph transformation to describe a deterministic computation, when we can apply two parallel dependent transformations to a graph  $G$

$$H1 \xrightarrow{p1,m1} G \Rightarrow \xrightarrow{p2,m2} H2$$

we have a possible conflict, which is solved if afterwards we can converge to a common result  $H$ :

A graph transformation is locally confluent if all conflicts can be solved.

## Confluence and Local Confluence

Confluence and local confluence are undecidable for graph transformation systems, even if they are terminating.

## Conflicts and Conflict detection

A **critical pair** is a minimal conflict: two direct transformations

$$P1 \xrightarrow{p1,m1} G \Rightarrow_{p2,m2} P2$$

such that they are not parallel independent and  $m1: L1 \rightarrow G$  and  $m2: L2 \rightarrow G$  are jointly epimorphic.

# Example: a Critical Pair

# Completeness Theorem

For any two parallel dependent direct transformations:

$$G1 \xleftarrow{p1,m1'} G' \Rightarrow_{p2,m2'} G2$$

there is a critical pair  $P1 \xleftarrow{p1,m1} G \Rightarrow_{p2,m2} P2$  such that:

# Strict Confluence

$P1 \xrightarrow{p1,m1} G \xRightarrow{p2,m2} P2$  is strictly confluent if there are morphisms  $f1$  and  $f2$  such that (1), (2), and (3) commute.

## Local Confluence Theorem

A graph transformation system is locally confluent if all its critical pairs are strictly confluent.

iThank You!
